Bah to PAHs!

INTERSTELLAR dust is responsible, through surface reactions, for the creation of molecular hydrogen, the main component of the interstellar clouds in which new stars form. Intermediate between small, gas-phase molecules and dust are the polycyclic aromatic hydrocarbons (PAHs). Such molecules could account for 2–30% of the carbon in the Galaxy<sup>1</sup>, and may provide nucleation sites for the formation of carbonaceous dust<sup>2,3</sup>. Although PAHs have been proposed<sup>4,5</sup> as the sources of the unidentified infrared emission

FIG. 1 Chemical structures representing the PAH molecules studied by SPIRES in this work. These include: four unsubstituted PAHs, phenanthrene (a,  $C_{14}H_{10}$ ), pyrene (b,  $C_{16}H_{10}$ ), perylene (c,  $C_{20}H_{12}$ ) and coronene (d,  $C_{24}H_{12}$ ); two methyl substituted PAHs, 2-methylnaphthalene (e,  $C_{11}H_{10}$ ), and 2-methylphenanthrene (f,  $C_{15}H_{12}$ ); and two hetero-substituted PAHs, phenanthridine, (g,  $C_{13}N_9N$ ) and dibenzofuran (h,  $C_{12}H_8O$ ). Molecules the size of coronene have recently been postulated to account for the 3.3- $\mu$ m UIR band<sup>20</sup>.

## The molecular universe: an interdisciplinary programme on the physics and chemistry of molecules in space

**Fact Sheet**

## Reporting

### Objective

Molecules are an important component of the universe which dominate the cooling and degree of ionization of interstellar gas clouds and, hence, regulate star and planet formation. The exploration of paths towards chemical complexity in space has direct bearing on the origin and evolution of life. Moreover, molecular transitions provide a sensitive probe of the dynamics and the physical and chemical conditions in a wide range of objects at scales ranging from newly formed planetary systems to galactic and extragalactic sizes. Near-future large scale observatories by the European Space Agency and the European Southern Observatory - in partnership with American and Far-East organizations - will open up the universe to high spatial and spectral resolution studies of molecules and, hence, the study of the key astrophysical and astrochemical processes involved in the formation and evolution of planets, stars, and galaxies. These new missions will lead to a multitude of molecular line data in a variety of astrophysical environments. Identification, analysis, and interpretation of this data in terms of the physical and chemical characteristics of the astronomical sources and the origin and evolution of the molecular universe will require a concerted effort by physicists, chemists, and astronomers in the areas of molecular spectroscopy, collisional excitation processes, chemical reactions, and astronomical modelling on species of astrophysical relevance. The results of this expert effort need to be made easily accessible to the scientific community through web-based data archives. The Research and Training Network on the Molecular Universe provides a cohesive framework for the training and development of researchers in the early stages of their career, combining European researchers in the areas of laboratory spectroscopy, laboratory astrochemistry, molecular quantum mechanical studies, astronomical modellers, and experts on data bases and web interfaces.

⇒ Occam's razor:

gas-phase reactions must be important

destruction routes are in the gas-phase

+ PAHs family

**1) What is the status of our knowledge of gas-phase reactions in the interstellar medium?**

**2) Can we expect new significant contributions to the understanding of the chemistry of interstellar objects from gas-phase chemistry?**

**1) What is the  
status of our  
knowledge of gas-  
phase reactions in  
the interstellar  
medium?**

# The chemical evolution of the interstellar medium: how do we study it?

**Laboratory experiments**

**modelling**

**observations**

Several thousands elementary reactions including:

- dissociation, excitation & ionization processes
- neutral-neutral reactions
- ion-molecule reactions
- heterogeneous processes

a large fraction of these processes still need to be characterized in lab experiments

GAS-PHASE M... NETWORK

too bad!

4,400 reactions; 10-20% "studied";  
450 species through 13 atoms in size

in 13 years this percentage has not

And those which have not been studied??  
... analogy with similar reactions or  
chemical intuition (and some imagination)...

Successes for quiescent cores:

Those which have been studied →  
... rarely have been studied under the  
appropriate conditions (low T, low P) ...

**What is the status of our knowledge of gas phase reactions?  
In particular, bimolecular reactions...**

interstellar clouds: 1) low T (as low as 10 K)  
2) low number density (as low as  $10^4 \text{ cm}^{-3}$ )

these are not favorable conditions for  
chemical transformations

What is the status of our knowledge of gas phase reactions?  
In particular, bimolecular reactions...

interstellar clouds: 1) low T (as low as 10 K)  
2) low number density (as low as  $10^4 \text{ cm}^{-3}$ )

these are not favorable conditions for  
chemical transformations

**these conditions are an  
absolute nightmare  
for lab experiments**

products

low density  $\Rightarrow$  few molecular encounters, little probability  
for chemical reactions to take place; absence of  
termolecular collisions (1 every  $10^9$  years)

# What is the status of our knowledge of gas phase reactions? In particular, bimolecular reactions...

in addition to that, most of the 8000 elementary reactions included in the astrochemical models involve either one or two transient species that must be produced in situ in lab experiments in a controlled manner

# What is the status of our knowledge of gas phase reactions? In particular, bimolecular reactions...

**we have three pillars**

❶ CRESU (Cinétique de Réaction en Ecoulement Supersonique Uniforme) technique

Rennes

low  $T$ , as low as those  
of interest in the ISM

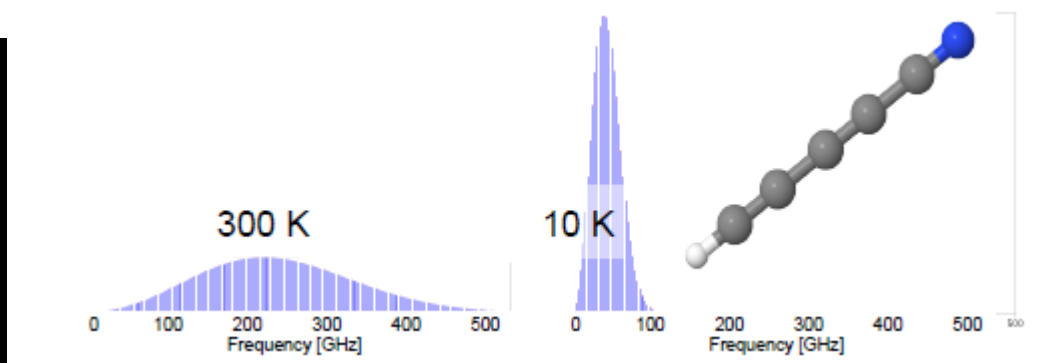

credit: S. Le Picard

**Laval nozzle** controls expansion of carrier gas: avoids problems of other cooling methods:

- expansion/cooling is rapid – **condensation avoided**
- expansion controlled – collisions **maintain thermal equilibrium**
- essentially a rapid temperature jump

credit: Ian Sims

Fantastic experimental technique that has twice revolutionised our common sense in astrochemistry: at the beginning of the 90's by proving that neutral-neutral reactions can be very fast at the low  $T$  of cold interstellar objects and now (see later)

**BUT** it does not provide a single-collision environment

# What is the status of our knowledge of gas phase reactions? In particular, bimolecular reactions...

**we have three pillars**

② collision free experiments (molecular beam experiments)

Crossed molecular  
beam method

Perugia

very low pressure  
(reactions under  
single collision  
conditions)

# The crossed molecular beam method: an experimental technique to study bimolecular reactions under single collision conditions

the colliding species are prepared by expanding the gases into two distinct molecular beams which cross each other at a specific angle and collision energy

⇒ the species of each beam are made to collide only with the molecules of the other beam at the collision center; the formed products fly undisturbed towards the detector

► because of the large mean free path, the products do not undergo secondary or wall collisions before arriving at the detector chamber

► this allows us to observe the consequences of (many) identical well-defined single molecular collisions ⇒ PRIMARY PRODUCTS

# Neutral-neutral reactions of astrophysical relevance investigated in Perugia:

# The rate of the $F + H_2$ reaction at very low temperatures

Meryem Tizniti<sup>1</sup>, Sébastien D. Le Picard<sup>1</sup>, François Lique<sup>2</sup>, Coralie Berteloite<sup>1</sup>, André Canosa<sup>1</sup>,  
Millard H. Alexander<sup>3\*</sup> and Ian R. Sims<sup>1\*</sup>

The prototypical  $F + H_2 \rightarrow HF + H$  reaction possesses a substantial energetic barrier ( $\sim 800$  K) and might therefore be expected to slow to a negligible rate at low temperatures. It is, however, the only source of interstellar HF, which has been detected in a wide range of cold (10–100 K) environments. In fact, the reaction does take place efficiently at low temperatures due to quantum-mechanical tunnelling. Rate constant measurements at such temperatures have essentially been limited to fast barrierless reactions, such as those between two radicals. Using uniform supersonic hydrogen flows we can now report direct experimental measurements of the rate of this reaction down to a temperature of 11 K, in remarkable agreement with state-of-the-art quantum reactive scattering calculations. The results will allow a stronger link to be made between observations of interstellar HF and the abundance of the most common interstellar molecule,  $H_2$ , and hence a more accurate estimation of the total mass of astronomical objects.

The potential energy surface and the non-BO method employed by M. Alexander had already been tested against crossed molecular beam experiments (for decades!!)

**Figure 3 | Comparison of rate coefficients  $k$  for the  $F(^2P_J) + n\text{-H}_2 \rightarrow \text{HF} + \text{H}$  reaction as a function of temperature.** Symbols present experimental results: from this work (filled red circles, with error bars corresponding to 95% confidence limits) and from Stevens and colleagues<sup>25</sup> (open triangles, with their quoted uncertainties). The solid and dashed blue lines represent the predictions of our scattering calculations with, respectively, inclusion and exclusion of non-BO coupling. In these calculations we assume a ratio of *ortho* ( $j = 1$ ) to *para* ( $j = 0$ )  $\text{H}_2$  of 3:1. Also shown is the Arrhenius temperature dependence proposed by Persky and Kornweitz<sup>28</sup> (alternating short-long dashed dark green line), the predictions of the single-PES quantum scattering calculations of Zhu and colleagues<sup>22</sup> (long-dashed magenta line) and the quantum reactive scattering calculations of Aquilanti and colleagues<sup>10,29</sup> (light green dashed-dotted line) performed on their PES III, which is a modification of the original Stark-Werner PES.

You can trust it 100%

**What is the status of our knowledge of gas phase reactions?  
In particular, bimolecular reactions...**

**we have three pillars**

**③ quantum chemistry calculations**

**a) There are no versatile experimental techniques achieving both low T and P:** a theoretical description of the reactive process via electronic structure calculations of the relevant potential energy surface + kinetics calculations can provide the rate coefficients under the conditions of interest; the comparison with available experimental data tests the accuracy of the calculations

**b) There are no experimental data at all:** a theoretical description of the reactive process via electronic structure calculations of the relevant potential energy surface + kinetics calculations can provide an educated guess of the reaction rate coefficients

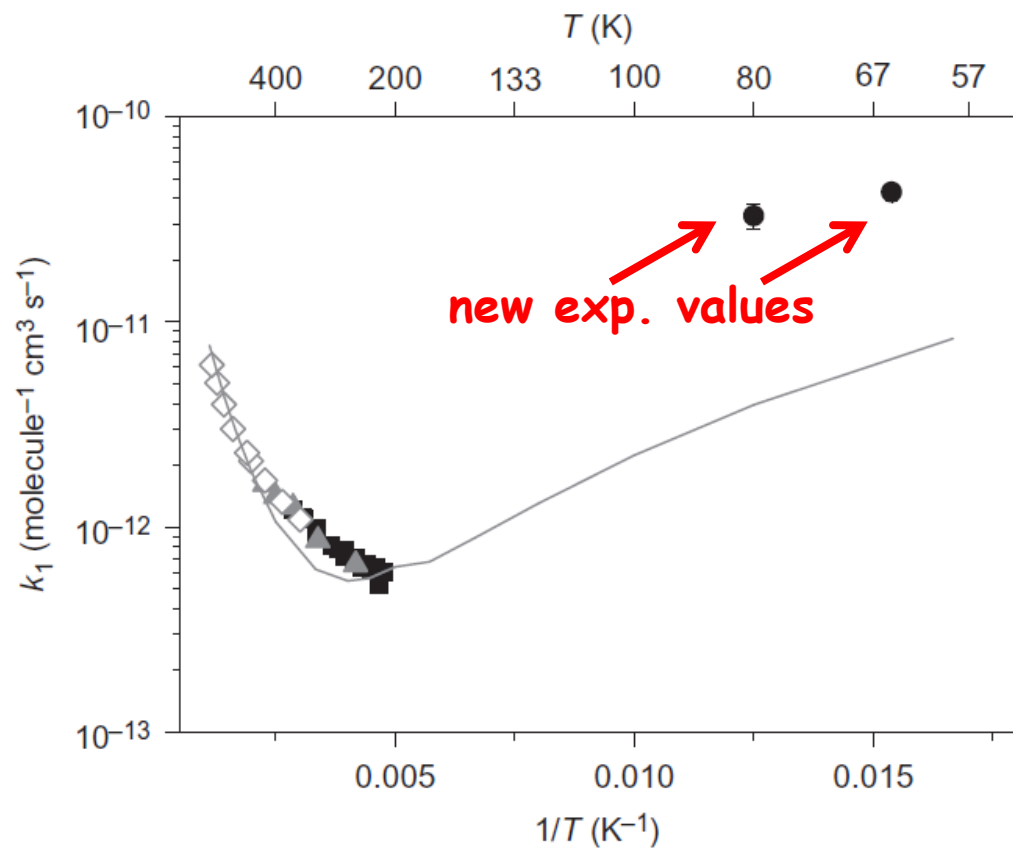

**2) Can we expect new significant contributions to the understanding of the chemistry of interstellar objects from gas-phase chemistry?**

# **1) recent CRESU results**

***the effects of pre-reactive  
complexes and tunnelling  
on rate coefficients***

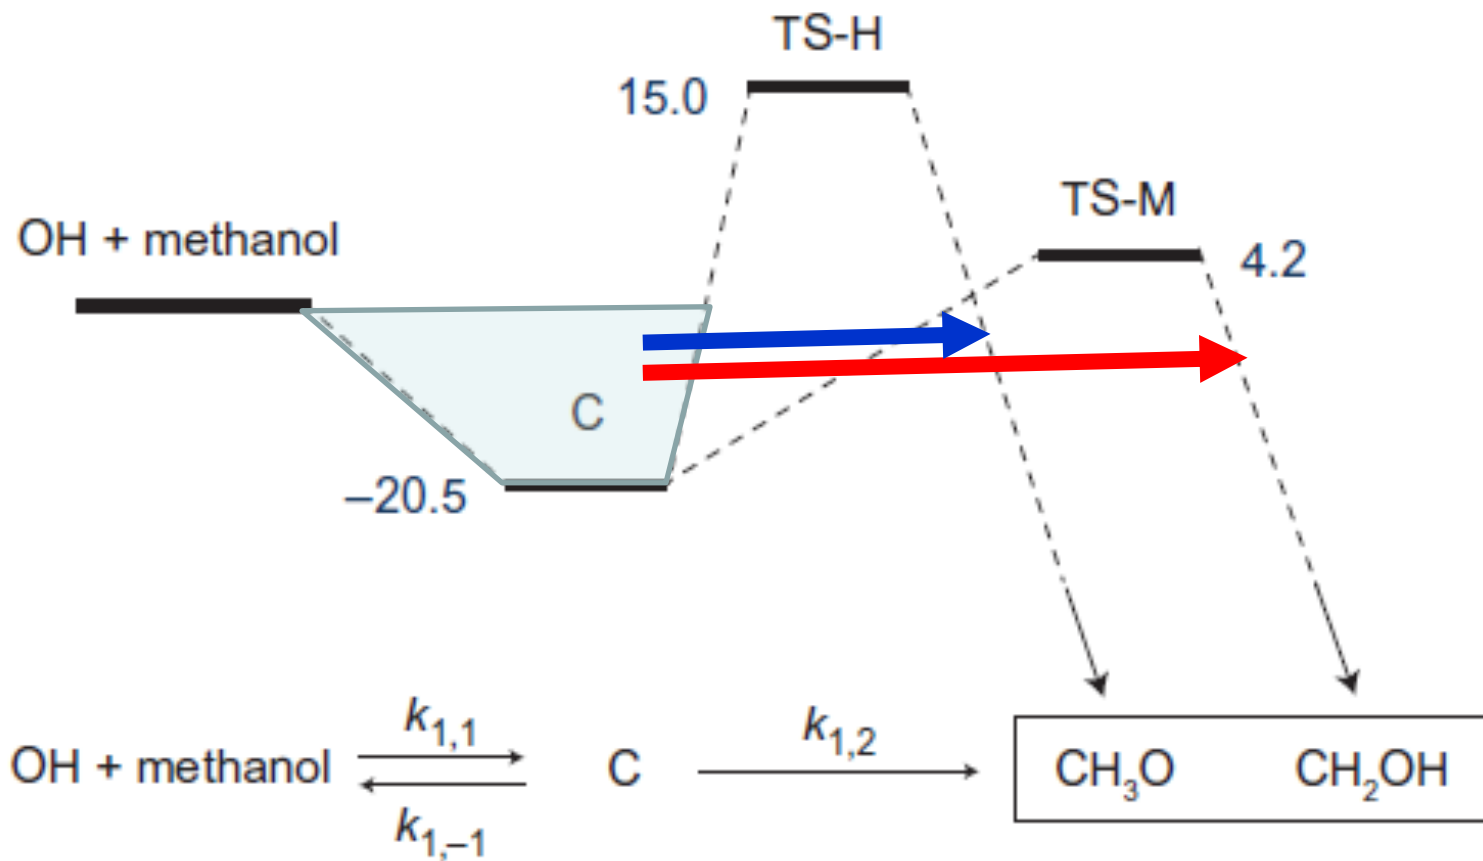

# Accelerated chemistry in the reaction between the hydroxyl radical and methanol at interstellar temperatures facilitated by tunnelling

Robin J. Shannon<sup>1</sup>, Mark A. Blitz<sup>1,2</sup>, Andrew Goddard<sup>1</sup> and Dwayne E. Heard<sup>1,2\*</sup>

Despite the presence of an entrance barrier, the rate coefficient at 63 K was found to be larger than the one at 200 K.

Deviations from Arrhenius behavior are quite common. In some cases they are associated to the tunnelling effect...

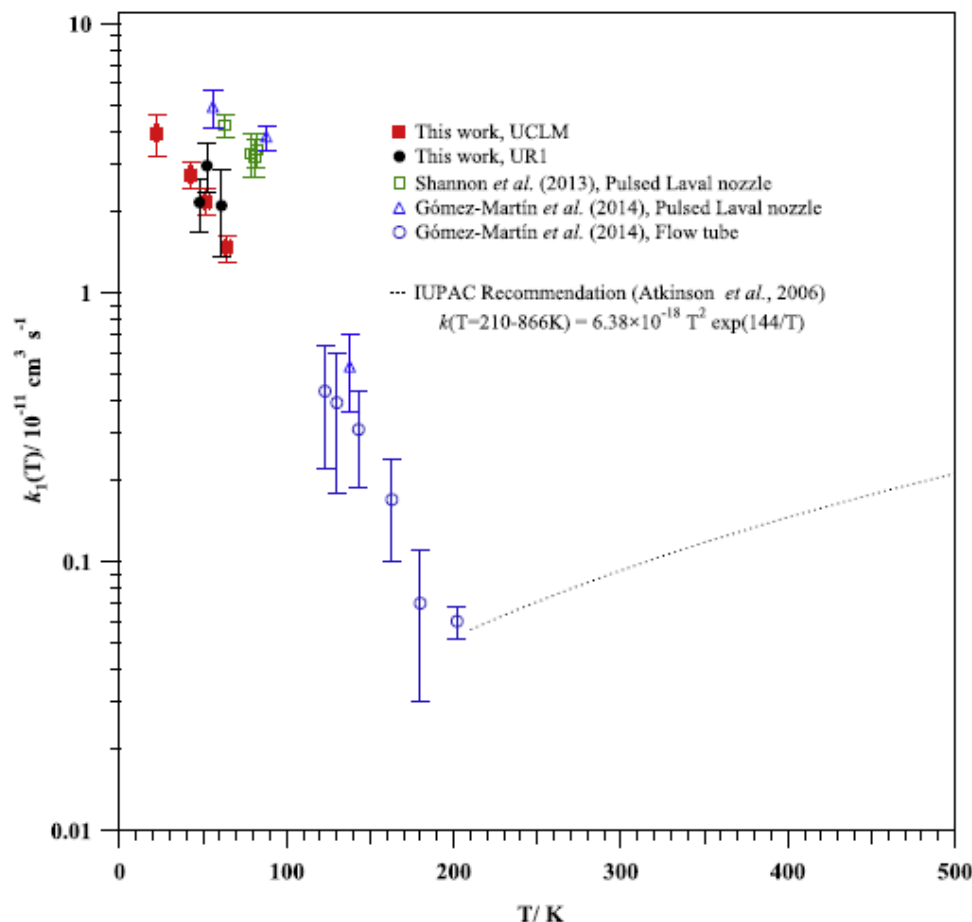

According to master equation calculations explicitly considering tunnelling effects, at temperatures lower than 200 K the lifetime of the van der Waals complex is very long and tunnelling towards CH<sub>3</sub>O+H becomes the dominant channel (99%)

# REACTIVITY OF OH AND CH<sub>3</sub>OH BETWEEN 22 AND 64 K: MODELING THE GAS PHASE PRODUCTION OF CH<sub>3</sub>O IN BARNARD 1b

## The astrochemical model (Nahoon + revised KIDA database)

The abundance of glycolaldehyde plotted against the abundance of ethanol for four different astrochemical objects follows closely the theoretical predictions based on our model (the three red curves correspond to different branching ratios of the ethanol radicals on hydrogen abstraction by the OH radical).

AND

ERIC HERBST

I. Physikalisches Institut, Universität zu Köln, Federal Republic of Germany

*Received 1988 May 16; accepted 1988 October 26*

For normal exothermic ion-molecule reactions we have assumed that the total rate coefficient is unchanged for deuterium analogs, e.g.,  $k_1 = k_2 + k_3$ , and have also assumed statistical branching ratios, e.g.,  $k_2 = k_3 = k_1/2$ . The first assumption is a reasonable one, since for all exothermic ion-molecule reactions in our model there is no significant activation energy barrier, and only small adjustments in rate due to reduced mass effects exist. The existence of a barrier, however, normally leads to important isotopic differences in rate. The second assumption is made for simplicity and lack of experimental evidence.

Still nowadays, it is common sense to consider gas phase reactions irrelevant in influencing the degree of deuteration of interstellar complex organic molecules.

# Kinetic isotope effect

Kinetic isotope effect (KIE) is the change in the reaction rate of a chemical reaction when one of the atoms in the reactants is replaced by one of its isotopes. Formally, it is the ratio of rate constants for the reactions involving the light ( $k_L$ ) and the heavy ( $k_H$ ) isotopically substituted reactants (from Wikipedia)

A primary kinetic isotope effect may be found when a bond to the isotopically-labeled atom is being formed or broken; in these cases

$$k_H / k_D \gg 1$$

A secondary kinetic isotope effect is observed when no bond to the isotopically-labeled atom in the reactant is broken or formed. Secondary kinetic isotope effects tend to be much smaller than primary kinetic isotope effects; it can be "normal"

$$k_H / k_D > 1$$

or "inverse"

$$k_H / k_D < 1$$

# Product branching ratios (BR)

- direct reactions (abstraction mechanism where a new X-H bond is formed) the H-products are favored (because of kinematics)
- indirect reactions (addition/insertion reactions where both an X-H or an X-D bond can be formed) the D-products are favored (the X-D bond is stronger than the X-H bond)

after 30 years from the paper by Millar, Bennet & Herbst it is time to move on

# Deuteration of interstellar complex organic molecules in gas-phase chemistry

## Case 1: formamide

## The ALMA-PILS survey: First detections of deuterated formamide and deuterated isocyanic acid in the interstellar medium

A. Coutens<sup>1</sup>, J. K. Jørgensen<sup>2</sup>, M. H. D. van der Wiel<sup>2</sup>, H. S. P. Müller<sup>3</sup>, J. M. Lykke<sup>2</sup>, P. Bjerkeli<sup>2,4</sup>, T. L. Bourke<sup>5</sup>, H. Calcutt<sup>2</sup>, M. N. Drozdovskaya<sup>6</sup>, C. Favre<sup>7</sup>, E. C. Fayolle<sup>8</sup>, R. T. Garrod<sup>9</sup>, S. K. Jacobsen<sup>2</sup>, N. F. W. Ligterink<sup>6</sup>, K. I. Öberg<sup>8</sup>, M. V. Persson<sup>6</sup>, E. F. van Dishoeck<sup>6,10</sup>, and S. F. Wampfler<sup>2</sup>

Assuming that the deuteration of formaldehyde in the region probed by the ALMA observations of formamide is similar to the value derived with single-dish observations ( $\sim 15\%$ , Loinard et al. 2000), we can discuss the possibility for the gas-phase formation mechanism proposed by Barone et al. (2015),  $\text{H}_2\text{CO} + \text{NH}_2 \rightarrow \text{NH}_2\text{CHO} + \text{H}$ . According to this reaction, the deuterated form NHDCHO would result from the reaction between NHD and  $\text{H}_2\text{CO}$ , while  $\text{NH}_2\text{CDO}$  would form from  $\text{NH}_2$  and HDCO. We would consequently expect a higher deuteration for  $\text{NH}_2\text{CDO}$ , compared to the observations, unless the reaction between  $\text{NH}_2$  and HDCO leads more efficiently to  $\text{NH}_2\text{CHO}$

and D, compared to  $\text{NH}_2\text{CDO}$  and H. Theoretical or experimental studies of the branching ratios of these reactions would be needed to rule out this scenario. The determination of the  $\text{HDCO}/\text{H}_2\text{CO}$  ratio from the PILS survey is also necessary. Nev-

## New quantum chemical computations of formamide deuteration support gas-phase formation of this prebiotic molecule

D. Skouteris,<sup>1★</sup> F. Vazart,<sup>1★</sup> C. Ceccarelli,<sup>2,3★</sup> N. Balucani,<sup>3,4</sup> C. Puzzarini<sup>3,5</sup>  
and V. Barone<sup>1</sup>

BR as expected  
 $\text{DCONH}_2 \gg \text{HCONH}_2$

KIE  
 $k_{\text{H}}/k_{\text{D}} \approx 3$

Reaction	A ( $\times 10^{-16} \text{cm}^3 \text{s}^{-1}$ )	$\beta$	$\gamma$ (K)	$k(T = 10 \text{ K})$	$k(T = 60 \text{ K})$ ( $\times 10^{-13} \text{cm}^3 \text{s}^{-1}$ )	$k(T = 100 \text{ K})$ ( $\times 10^{-13} \text{cm}^3 \text{s}^{-1}$ )
(1) $\text{NH}_2 + \text{HDCO} \rightarrow \text{DCONH}_2 + \text{H}$	20.7	-2.75	4.34	153	1.60	0.41
(2) $\text{NH}_2 + \text{HDCO} \rightarrow \text{HCONH}_2 + \text{D}$	1.08	-2.15	0.96	1.49	0.03	0.01
(3) $\text{NHD} + \text{H}_2\text{CO} \rightarrow \text{trans-HCONHD} + \text{H}$	30.7	-2.63	5.05	141	1.93	0.52
(4) $\text{NHD} + \text{H}_2\text{CO} \rightarrow \text{cis-HCONHD} + \text{H}$	26.2	-2.64	5.04	126	1.69	0.45
(5) $\text{NH}_2 + \text{H}_2\text{CO} \rightarrow \text{HCONH}_2 + \text{H}$	77.9	-2.56	4.88	287	4.41	1.23

Our prediction: the deuteration of formamide synthesized in the gas-phase will be 3 times smaller than that of the parent species  $\text{NH}_2$  and  $\text{H}_2\text{CO}$

A few months later: the best estimate  $\text{HDCO}/\text{H}_2\text{CO}$  is 3 times higher than  $\text{NH}_2\text{CDO}/\text{NH}_2\text{CHO}$

(i)  $\text{DCONH}_2/\text{HCONH}_2$  and  $\text{HCONHD}/\text{HCONH}_2$  abundance ratios smaller than  $\text{HDCO}/\text{H}_2\text{CO}$ . The values in Table 2 show that there is a factor of 3 difference in the rates of formation of H- against D-formamide. Therefore, the deuteration of formamide synthesized in the gas phase will be three times smaller than that of the mother molecules  $\text{NH}_2$  and  $\text{H}_2\text{CO}$ . No observations

## The ALMA-PILS survey: Formaldehyde deuteration in warm gas on small scales toward IRAS 16293–2422 B

M. V. Persson<sup>1,2</sup>, J. K. Jørgensen<sup>3</sup>, H. S. P. Müller<sup>4</sup>, A. Coutens<sup>5</sup>, E. F. van Dishoeck<sup>2,6</sup>, V. Taquet<sup>7</sup>, H. Calcutt<sup>2</sup>, M. H. D. van der Wiel<sup>8</sup>, T. L. Bourke<sup>9</sup>, and S. Wampfler<sup>10</sup>

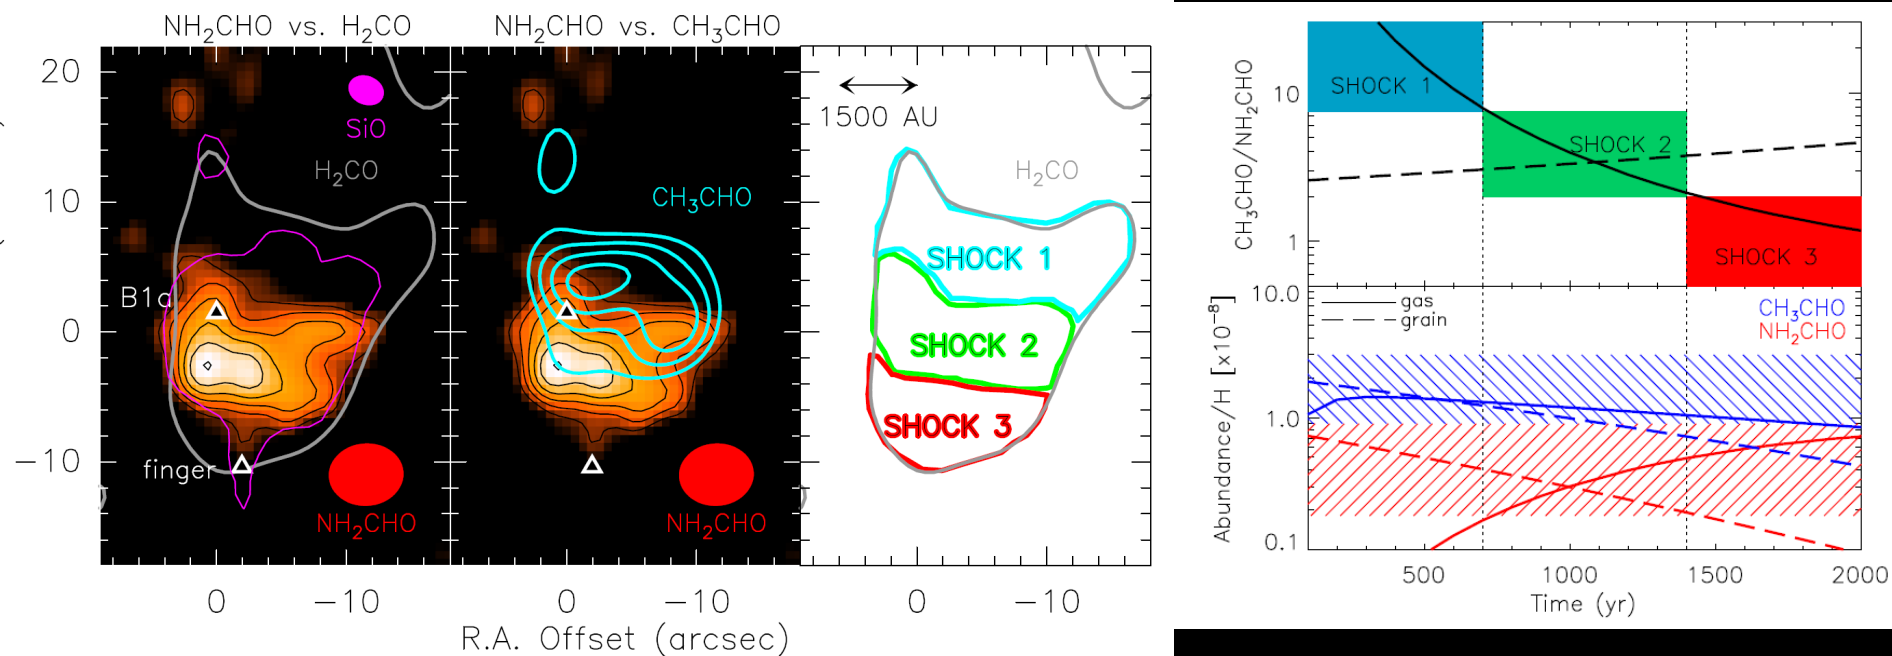

2% assuming a standard  $^{12}\text{C}/^{13}\text{C}$  ratio of 68. Skouteris et al. (2017) also calculated the rate coefficients of the reactions producing deuterated formamide. Consequently, a comparison of the deuteration of formamide and formaldehyde can help determine if this gas phase pathway (for formamide) is possible or if it has to be ruled out in this source. According to the respective rate coefficients determined for  $\text{NH}_2\text{CHO}$  and  $\text{NH}_2\text{CDO}$  by Skouteris et al., the  $\text{HDCO}/\text{H}_2\text{CO}$  ratio should be three times higher than the  $\text{NH}_2\text{CDO}/\text{NH}_2\text{CHO}$  ratio if this gas-phase reaction occurs. At similar spatial scales, the best estimate  $\text{HDCO}/\text{H}_2\text{CO}$  ratio is  $6.5 \pm 1\%$ , i.e. approximately three times higher than the  $\text{NH}_2\text{CDO}/\text{NH}_2\text{CHO}$  ratio. Thus, a gas phase formation pathway
